27 /// Demultiplex one AXI4+ATOP slave port to multiple AXI4+ATOP
28 /// master ports.
29 ///
30 /// The AW and AR slave channels each have a `select` input to
31 /// determine to which master port the
32 /// current request is sent. The `select` can, for example,
33 /// be driven by an address decoding module
34 /// to map address ranges to different AXI slaves.
35 ///
36 /// ## Design overview
37 ///
38 /// [Block diagram](module.axi_demux.png "Block diagram")
39 ///
40 /// Beats on the W channel are routed by demultiplexer accord-
41 /// ing to the selection for the
42 /// corresponding AW beat. This relies on the AXI property
43 /// that W bursts must be sent in the same
44 /// order as AW beats and beats from different W bursts may
45 /// not be interleaved.
46 ///
47 /// Beats on the B and R channel are multiplexed from the mas-
48 /// ter ports to the slave port with
49 /// a round-robin arbitration tree.

```

APB

What this is. The APB peripheral bus.

Why it exists. Because not everything needs AXI. Configuration registers and slow peripherals are better served by a simple non-pipelined bus, and bridging AXI to APB is standard practice.

Undergraduate review · EECS concepts. Simple bus protocols; address decoding; bridging between protocols.

Graduate · Practice note. APB's simplicity is its value: a peripheral with an APB interface is trivial to verify and to integrate. Consider it for any block whose bandwidth is not the point.

11 // APB Clock Domain Crossing
12 // Author: Manuel Eggimann <eggimann@iis.ee.ethz.ch>
13 // Description: A clock domain crossing module on an APB in-
  terface. The module uses gray-counting
14 // CDC FIFOs in both directions to synchronize source side
  with destination side.
15 // Parameters:
16 // - `LogDepth`: The FIFO crossing the clock domain has
  `2*LogDepth` entries
17 // - `req_t`: APB4 request struct. See macro definition in
  `include/typedef.svh`
18 // - `resp_t`: APB4 response struct. See macro defini-
  tion in `include/typedef.svh`

```

```

19 //
20 // Ports:
21 //
22 // - `src_pclk_i`: Source side clock input signal (1-bit).
23 // - `src_preset_ni`: Source side asynchronous active low reset
  signal (1-bit).
24 // - `src_req_i`: Source side APB4 request struct, bundles
  all APB4 signals from the master (req_t).
25 // - `src_resp_o`: Source side APB4 response struct, bundles
  all APB4 signals to the master (resp_t).
26 // - `dst_pclk_i`: Destination side clock input signal (1-
  bit).
27 // - `dst_preset_ni`: Destination side asynchronous active low
  reset signal (1-bit).
28 // - `dst_req_o`: Destination side APB4 request struct,
  bundles all APB4 signals to the slave (req_t).
29 // - `dst_resp_i`: Destination side APB4 response struct,
  bundles all APB4 signals from the slave (resp_t).
30 //
31 // This file also features the module `apb_cdc_intf`. The dif-
  ference is that instead of the
32 // request and response structs it uses a `APB` interfaces.
  The parameters have the same
33 // function, however are defined in `ALL_CAPS`.

11 // APB Read-Write Registers
12 // Description: This module exposes a number of registers on
an APB interface.
13 // It responds to not mapped accesses with a
slave error.
14 // Some of the registers can be configured to be
read only.
15 // Parameters:
16 // - `NoApbRegs`: Number of registers.
17 // - `ApbAddrWidth`: Address width of `req_i.paddr`, is used
to generate internal address map.
18 // - `AddrOffset`: The address offset in bytes between the
registers. Is asserted to be a least
19 // `32'd4`, the reason is to prevent overlap in
the address map.
20 // Each register is mapped to a 4 byte wide
address range. When this parameter
21 // is bigger than `32'd4` there will be
holes in the address map and the module
22 // answers with `apb_pkg::RESP_SLVERR`. It
is recommended that this value is a
23 // power of 2, to prevent data alignment is-
sues on upstream buses.
24 // - `ApbDataWidth`: The data width of the APB4 bus, this
value can be up to `32'd32` (bit).
25 // - `RegDataWidth`: The data width of the registers, this
value has to be less or equal to
26 // `ApbDataWidth`. If it is less the re-
gister gets zero extended for reads and
27 // higher bits on writes get ignored.
28 // - `ReadOnly`: This flag can specify a read only re-
gister at the given register index of the
29 // array. When in the array the correspond-
ing bit is set, the `reg_init_i` signal
30 // at given index can be read out. Writes
are ignored if the flag is set.
31 // - `req_t`: APB4 request struct. See macro definition in
`include/typedef.svh`
32 // - `resp_t`: APB4 response struct. See macro defini-
tion in `include/typedef.svh`
33 //
34 // Ports:
35 //
36 // - `pclk_i`: Clock input signal (1-bit).
37 // - `preset_ni`: Asynchronous active low reset signal (1-
bit).
38 // - `req_i`: APB4 request struct, bundles all APB4
signals from the master (req_t).
39 // - `resp_o`: APB4 response struct, bundles all APB4
signals to the master (resp_t).
40 // - `base_addr_i`: Base address of this module, from here
the registers `0` are mapped, starting
41 // with index `0`. All subsequent register
with higher indices have their bases
42 // mapped with reg_index * `AddrOffset` from
this value (ApbAddrWidth-bit).
43 // - `reg_init_i`: Initialization value for each register,
when the register index is configured

```

```

44 // as `ReadOnly[reg_index] == 1'b1` this
value is passed through directly to
45 // the APB4 bus (Array size `NoApbRegs` *
RegDataWidth-bit).
46 // - `reg_q_o`: The current value of the register. If the
register at the array index is
47 // read only, the `reg_init_i` value is
passed through to the respective index
48 // (Array size `NoApbRegs` * RegDataWidth-
bit).
49 //
50 // This file also features the module `apb_regs_intf`. The
difference is that instead of the
51 // request and response structs it uses an `APB.Salve` inter-
face. The parameters have the same
52 // Function, however are defined in `ALL_CAPS`.

RISC-V 디버그

What this is. The PULP RISC-V debug module.

Why it exists. Because **debug must work when nothing else does**, which is why it is a separate module with its own transport and clocking.

Undergraduate review · EECS concepts. JTAG; debug transport modules; abstract commands; program buffers.

Graduate · Practice note. Compare with the OpenTitan debug module: both implement the same specification with different structural choices, which is a useful exercise in reading two implementations of one document.

25 // Design Name: OBI Wrapper for Debug Module
26 // (dm_top)
27 // Project Name:
28 // CV32E40P
29 // Language: SystemVeri-
30 // log
31 //
32 //
33 // Description: Wrapper for the Debug Module (dm_top) which
34 // gives it an // OBI (Open Bus Interface) compatible inter-
35 // faces so that it // can be integrated without further glue lo-
36 // gic (other than // tie offs in an OBI compliant sys-
37 // tem.
38 //
39 //
40 // This wrapper is only intended for OBI com-
41 // pliant systems; //
42 //
43 // in other systems the existing dm_top can be
44 // used as before // and this wrapper can be ig-
45 // nored.
46 //
47 //
48 // The OBI spec is available

```

CV32E40P RISC-V 코어

What this is. A 32-bit RISC-V core with PULP extensions, taped out in several projects.

Why it exists. Because it is the design under test in the **step-and-compare methodology** described in the verification chapters, and small enough to read completely.

Undergraduate review · EECS concepts. Pipelining; hazard detection and forwarding; exception handling; CSR implementation.

Graduate · Practice note. Read the decode stage first, then the controller. Nearly all of a small core's complexity is in hazard and exception control, not in the datapath.

CV32E40P RVFI 트레이스

What this is. The RISC-V Formal Interface instrumentation for the core: retirement trace output.

Why it exists. Because model and RTL cannot be compared unless the RTL reports what it did. This module exposes, per retired instruction, the PC, the instruction word, register reads and writes, memory accesses and traps.

Undergraduate review · EECS concepts. Observability; trace interfaces; instrumentation that does not alter behaviour.

Graduate · Practice note. If your project lacks an equivalent interface, **building one is the highest-value first task** a new modelling engineer can undertake: nothing else in the comparison flow can exist without it.

PicoRV32 -- 초소형 RISC-V

What this is. A very small RISC-V core, widely used in FPGA designs.

Why it exists. Because it shows how little is needed for a working processor. It trades cycles per instruction for area and is the clearest introduction to RISC-V RTL.

Undergraduate review · EECS concepts. Multi-cycle versus pipelined execution; area–performance trade-offs; simple bus interfaces.

Graduate · Practice note. A good first core to read end to end. Understanding one complete core makes reading a complex one far easier.

13 files • 5,076 lines

SERV -- 비트직렬 RISC-V

What this is. A bit-serial RISC-V core — among the smallest in existence.

Why it exists. Because it demonstrates the extreme of the area–time trade. Processing one bit per cycle makes the datapath almost disappear, at 32× the cycle count.

Undergraduate review · EECS concepts. Bit-serial arithmetic; area–time product; extreme resource constraint.

Graduate · Practice note. Worth reading as an existence proof: many datapaths can be serialised when area matters more than latency, and the technique is under-used.

173 generate
174  /*
175  Because SERV is 32-bit bit-serial we need a counter
than can count 0-31
176
177  to keep track of which bit we are currently processing.
o_cnt and cnt_r
178  are used together to create such a counter.
The top three bits (o_cnt) are implemented as a normal

```

counter, but

```

179      instead of the two LSB, cnt_r is a 4-bit shift register
which loops 0-3
180      When cnt_r[3] is 1, o_cnt will be increased.
181
182      The counting starts when the core is idle and the
i_rf_ready signal
183      comes in from the RF module by shifting in the
i_rf_ready bit as LSB of
184      the shift register. Counting is stopped by using
o_cnt_done to block the
185      bit that was supposed to be shifted into bit 0 of
cnt_r.
186
187      There are two benefit of doing the counter this way
188
189      1. We only need to check four bits instead of five when
we want to check
190      if the counter is at a certain value. For 4-LUT archi-
tectures this means
191      we only need one LUT instead of two for each comparis-
on.
192
193      2. We don't need a separate enable signal to turn on
and off the counter
194      between stages, which saves an extra FF and a unique
control signal. We
195      just need to check if cnt_r is not zero to see if the
counter is
196      currently running
197      */

형식검증된 AXI/Wishbone 브리지

What this is. A bridge between Wishbone and AXI, developed with formal verification throughout.

Why it exists. Because a bus bridge is where protocol violations are introduced, and because protocol conformance is exactly the kind of local, bounded property that formal methods settle completely.

Undergraduate review · EECS concepts. Formal property verification; protocol assertions; induction and bounded model checking.

Graduate · Practice note. Read the assertions before the implementation. They are a precise, executable statement of the AXI rules and are more instructive than the protocol specification's prose.

```

1 ///////////////////////////////////////////////////////////////////
2 //
3 // Filename:    rtl/addrdecode.v
4 // {{{
5 // Project:    WB2AXIPSP: bus bridges and other odds and ends
6 //
7 // Purpose:    Supports bus crossbars by answering the ques-
tion, which slave
8 //
9 // does the current address need to be routed to? Re-
quests are
10 // pipelined using valid!/stall handshaking. For those
familiar with
11 // AXI, READY!=STALL. The outgoing stream is identical to
the incoming
12 // one, save for the (new) o_decode field. This is a bit-
mask containing
13 // one bit for each slave that the request might be routed
to, and one
14 // extra bit to indicate no slaves matched.
15 //
16 // The keys to the operation of this module are found in
the two
17 // parameters, SLAVE_ADDR and SLAVE_MASK.
18 //
19 // SLAVE_ADDR specifies the address of the slave in ques-
tion. It's a large
20 // array, with one address (i.e. one set of AW
bits) for each
21 // potential slave address region.
22 //
23 // SLAVE_MASK specifies which of the bits in SLAVE_ADDR
need to match in
24 // order to route a request to a that slave.
25 //
26 // It's important to guarantee that no two slaves will
ever map to the

```

```

26 // same address, and likewise any given slave may only map to
a single
27 // address region.
28 //
29 // Incidentally, the algorithm forces all slaves to have
an address
30 // aligned with their memory size. Hence a 2GB memory
must have an
31 // address (range) of either 0-2GB, 2GB-4GB, 4GB-6GB,
etc. However, a
32 // second slave having only 8kB of memory may be placed at
0-8kB,
33 // 8-16kB, 16-24kB, etc. For logic minimization purposes, it
is often to
34 // the advantage of the bus compositor to minimize the
number of mask
35 // bits, and hence 8kB slaves may be aliased to many
places in memory.
36 // Bus composition and address assignment, however, are
both outside of
37 // the scope of the operation of this module.
38 //

3 // Filename:      rtl/axi2axi3.v
4 // {{{
5 // Project:      WB2AXIPSP: bus bridges and other odds and ends
6 //
7 // Purpose:      Bridge from an AXI4 slave to an AXI3 master
8 //
9 // The goal here is to not lose bus resolution, capacity
or capability,
10 // while bridging from AXI4 to AXI3. The biggest problem
with such
11 // a bridge is that we'll need to break large requests
(AxLEN>15) up
12 // into smaller packets. After that, everything should
work as normal
13 // with only minor modifications for AxCACHE.
14 //
15 // Opportunity:
16 // The cost of this core is very much determined by the
number of ID's
17 // supported. It should be possible, with little extra
cost or effort,
18 // to reduce the ID space herein. This should be a topic
for future
19 // exploration.
20 //
21 // Status:
22 // This core is an unverified first draft. It has past
neither formal
23 // nor simulation testing. Therefore, it is almost cer-
tain to have bugs
24 // within it. Use it at your own risk.

5 // Project:    WB2AXIPSP: bus bridges and other odds and ends
6 //
7 // Purpose:    Convert from AXI to AXI-lite with no performance loss.
8 //
9 // Performance: The goal of this converter is to convert from AXI to AXI-lite
10 //              while still maintaining the one-clock per transaction speed
11 //              of AXI. It currently achieves this goal. The design needs very little
12 //              configuration to be useful, but you might wish to resize the FIFOs
13 //              within depending upon the length of your slave's data path. The current
14 //              FIFO length, LGFIFO=4, is sufficient to maintain full speed. If the
15 //              slave, however, can maintain full speed but requires a longer
16 //              processing cycle, then you may need longer FIFOs.
17 //
18 //              The AXI specification does require an additional 2 clocks per
19 //              transaction when using this core, so your latency will go up.
20 //
21 // Related:    There's a related axidoube.v core in the same repository as
22 //              well. That can be used to convert the AXI protocol to something
23 //              simpler (even simpler than AXI-lite), but it can also do so for multiple
24 //              downstream slaves at the same time.

PCIe 코어

What this is. PCIe interface logic: transaction layer, data link layer, DMA.

Why it exists. Because **PCIe is the dominant system interconnect**, and because its layering shows how ordering rules, credit flow control and replay interact.

Undergraduate review · EECS concepts. Layered protocols; credit-based flow control; packet ordering rules; retry mechanisms.

Graduate · Practice note. PCIe ordering rules (posted, non-posted, completion) are a frequent source of subtle bugs. They are worth studying as a specification-reading exercise in their own right.

RVFI UVM 에이전트

What this is. A UVM agent that monitors the RVFI interface and checks its properties.

Why it exists. Because the trace must be captured and checked, not merely emitted. The agent turns retirement events into transactions a scoreboard can consume.

Undergraduate review · EECS concepts. UVM agent structure (driver, monitor, sequencer); transaction-level modelling; assertions.

Graduate · Practice note. This is the bridge between the RTL's observability and the comparison logic. Studying it shows concretely how a verification environment is layered.

step-compare 테스트벤치

What this is. The testbench that steps a reference ISS and the RTL core together and compares architectural state after every retired instruction.

Why it exists. Because it is the operational definition of a bug in a CPU project: model and design disagree. It compares the PC, all 32 general-purpose registers and the CSRs.

Undergraduate review · EECS concepts. Reference-model comparison; scoreboarding; masking of implementation-defined state.

Graduate · Practice note. Read the comments. One records that static register checks were disabled because bus stalls made them fail — a real engineering compromise between coverage and usability, documented in place. **That is what honest verification code looks like.**
